## Homotopy of Curves

## Homotopy of Curves

## Definition

Let  $X$  be a topological space. Two curves  $u, v$  from  $a$  to  $b$  in  $X$  are called homotopic if there exists a continuous mapping  $A: I \times I \rightarrow X$  with the following properties:

- (i)  $A(t, 0) = u(t) \forall t \in I$
- (ii)  $A(t, 1) = v(t) \forall t \in I$
- (iii)  $A(0, s) = a, A(1, s) = b \forall s \in I$

Denote:  $u \sim v$

## Homotopy of Curves

## Homotopy of Curves

## Definition

Let  $X$  be a topological space. Two curves  $u, v$  from  $a$  to  $b$  in  $X$  are called homotopic if there exists a continuous mapping  $A: I \times I \rightarrow X$  with the following properties:

- (i)  $A(t, 0) = u(t) \forall t \in I$
- (ii)  $A(t, 1) = v(t) \forall t \in I$
- (iii)  $A(0, s) = a, A(1, s) = b \forall s \in I$

Denote:  $u \sim v$

**Remark** By setting  $u_s(t) := A(t, s)$  we have a family  $(u_s)_{s \in I}$  of curves from  $a$  to  $b$ , called a deformation of  $u$  into  $v$ .

## Homotopy of Curves

### Homotopy of Curves

#### Theorem

*The notion of homotopy is an equivalence relation on the set of all curves from  $a$  to  $b$ .*

From now, for any curve  $u$  in  $X$  we denote its homotopy class by  $cl(u)$ .

## Homotopy of Curves

## Homotopy of Curves

## Definition

Let  $a, b, c$  be 3 points in  $X$ . Suppose  $u$  is a curve from  $a$  to  $b$  and  $v$  is a curve from  $b$  to  $c$ . Define:

- (i) The product curve:  $(u \cdot v)(t) := \begin{cases} u(2t) & \text{if } t \in [0, \frac{1}{2}] \\ v(2t - 1) & \text{if } t \in [\frac{1}{2}, 1] \end{cases}$ .
- (ii) The inverse curve:  $u^-(t) := u(1 - t) \forall t \in [0, 1]$ .
- (iii) The constant curve at  $a$ :  $u_0(t) := a \forall t \in [0, 1]$ .

## Homotopy of Curves

## Homotopy of Curves

## Theorem

Let  $a, b, c, d \in X$ . Suppose  $u$  (resp.  $v, w$ ) is a curve from  $a$  to  $b$  (resp. from  $b$  to  $c$ , from  $c$  to  $d$ ) and  $u_0$  (resp.  $v_0$ ) is the constant curve at  $a$  (resp.  $b$ ). Then:

- (i)  $u_0 \cdot u \sim u \sim u \cdot v_0$ .
- (ii)  $u \cdot u^{-1} \sim u_0$ .
- (iii)  $(u \cdot v) \cdot w \sim u \cdot (v \cdot w)$ .

## Homotopy of Curves

### The Fundamental Group

#### Theorem (The fundamental group)

*The set  $\pi_1(X, a)$  of homotopy classes of closed curves in  $X$  with initial point and end point  $a$  forms a group under the operation induced by the product of curves. This group is called the fundamental group of  $X$  with base point  $a$ .*

## Homotopy of Curves

### The Fundamental Group

#### Theorem (Dependence of the base point)

If there exists a curve  $w$  joining  $a$  and  $b$  then  $\pi_1(X, a) \cong \pi_1(X, b)$ .

## Homotopy of Curves

## The Fundamental Group

## Theorem (Dependence of the base point)

If there exists a curve  $w$  joining  $a$  and  $b$  then  $\pi_1(X, a) \cong \pi_1(X, b)$ .

Hint: The isomorphism  $f : \pi_1(X, a) \rightarrow \pi_1(X, b)$  is given by

$$f(\text{cl}(u)) := \text{cl}(w^{-1} \cdot u \cdot w).$$

## The Fundamental Group

### Theorem (Dependence of the base point)

If there exists a curve  $w$  joining  $a$  and  $b$  then  $\pi_1(X, a) \cong \pi_1(X, b)$ .

Hint: The isomorphism  $f : \pi_1(X, a) \rightarrow \pi_1(X, b)$  is given by

$$f(\text{cl}(u)) := \text{cl}(w^{-1} \cdot u \cdot w).$$

**Remark** When  $X$  is arcwise connected, the fundamental group  $\pi_1(X, a)$  is independent of the base point so we just write  $\pi_1(X)$ .

## Homotopy of Curves

## Functorial Behavior

Suppose  $f : X \rightarrow Y$  is a continuous mapping. If  $u$  is a curve in  $X$  then  $f \circ u$  is a curve in  $Y$ . Moreover, if  $u \sim u'$  in  $X$  then  $f \circ u \sim f \circ u'$  in  $Y$ . Hence  $f$  induces a homomorphism:

$$f_* : \pi_1(X, a) \rightarrow \pi_1(Y, f(a))$$

Moreover, if  $g : Y \rightarrow Z$  is another continuous mapping, one has:

$$(g \circ f)_* = g_* \circ f_*$$

## The Coverings of Riemann Surfaces

### Ramification points of a holomorphic mapping

#### Recall

Let  $p : Y \rightarrow X$  be a non-constant holomorphic mapping. Suppose  $p(y_0) = x_0$ , then there exists charts  $(U, \phi)$  of  $X$ ,  $(V, \psi)$  of  $Y$  such that the map  $F := \phi \circ p \circ \psi^{-1}$  has the form  $F(z) = z^k$ , for some interger  $k \geq 1$ .

## The Coverings of Riemann Surfaces

### Ramification points of a holomorphic mapping

#### Recall

Let  $p : Y \rightarrow X$  be a non-constant holomorphic mapping. Suppose  $p(y_0) = x_0$ , then there exists charts  $(U, \phi)$  of  $X$ ,  $(V, \psi)$  of  $Y$  such that the map  $F := \phi \circ p \circ \psi^{-1}$  has the form  $F(z) = z^k$ , for some interger  $k \geq 1$ .

#### Definition

A point  $y_0$  is called a ramification point (or branch point) of  $p$  if the number  $k$  in the local description is greater or equal to 2.  
The number  $k$  is called the ramification order of the ramification point  $y_0$ .  
If the map  $p$  has no branch points, then we call it unbranched.

## Theorem

Let  $p : Y \rightarrow X$  be a non-constant holomorphic map. Then  $p$  is unbranched if and only if  $p$  is a local homeomorphism.

### Theorem

Let  $p : Y \rightarrow X$  be a non-constant holomorphic map. Then  $p$  is unbranched if and only if  $p$  is a local homeomorphism.

### Theorem

Suppose  $X$  is a Riemann surface,  $Y$  is a Hausdorff space and  $p : Y \rightarrow X$  is a local homeomorphism. Then there is a unique complex structure on  $Y$  such that  $p$  is holomorphic. ( $p$  is even locally biholomorphic).

## The Coverings of Riemann Surfaces

### The Topological Coverings

#### Definition

- (i) Let  $p: Y \rightarrow X$  be a continuous map between topological spaces. For each  $x \in X$ , the set  $p^{-1}(x)$  is called the fiber of  $p$  over  $x$ . The map  $p$  is said to be discrete if every fiber of  $p$  is a discrete subset of  $Y$ .

## The Coverings of Riemann Surfaces

### The Topological Coverings

#### Definition

- (i) Let  $p : Y \rightarrow X$  be a continuous map between topological spaces. For each  $x \in X$ , the set  $p^{-1}(x)$  is called the fiber of  $p$  over  $x$ . The map  $p$  is said to be discrete if every fiber of  $p$  is a discrete subset of  $Y$ .
- (ii) If  $q : Z \rightarrow X$  is another continuous map, then a map  $f : Y \rightarrow Z$  is called a fiber preserving map if  $p = q \circ f$ .

$$\begin{array}{ccc} Y & \xrightarrow{f} & Z \\ \downarrow p & & \swarrow q \\ X & & \end{array}$$

## The Coverings of Riemann Surfaces

### The Topological Coverings

- (ii) If  $q : Z \rightarrow X$  is another continuous map, then a map  $f : Y \rightarrow Z$  is called a fiber preserving map if  $p = q \circ f$ .

$$\begin{array}{ccc} Y & \xrightarrow{f} & Z \\ \downarrow p & & \swarrow q \\ X & & \end{array}$$

**Remark** A non-constant holomorphic map  $p : Y \rightarrow X$  between 2 Riemann surfaces is discrete.

## Definition (The Lifting of Mappings)

Suppose  $X, Y, Z$  are topological spaces,  $p : Y \rightarrow X$  and  $f : Z \rightarrow X$  are continuous maps. Then by a lifting of  $f$  with respect to  $p$  is meant a continuous mapping  $g : Z \rightarrow Y$  such that  $f = p \circ g$ .

$$\begin{array}{ccc} & & Y \\ & \nearrow g & \downarrow p \\ Z & \xrightarrow{f} & X \end{array}$$

## Definition (The Lifting of Mappings)

Suppose  $X, Y, Z$  are topological spaces,  $p : Y \rightarrow X$  and  $f : Z \rightarrow X$  are continuous maps. Then by a lifting of  $f$  with respect to  $p$  is meant a continuous mapping  $g : Z \rightarrow Y$  such that  $f = p \circ g$ .

$$\begin{array}{ccc} & & Y \\ & \nearrow g & \downarrow p \\ Z & \xrightarrow{f} & X \end{array}$$

## Theorem (Holomorphicity of Lifting)

Suppose  $X, Y, Z$  are Riemann surfaces,  $p : Y \rightarrow X$  is an unbranched holomorphic map and  $f : Z \rightarrow X$  is any holomorphic map. Then every lifting  $g : Z \rightarrow Y$  of  $f$  is holomorphic.

## Theorem (Uniqueness of Lifting)

Let  $X, Y$  be Hausdorff spaces and  $p : Y \rightarrow X$  be a local homeomorphism. Suppose  $Z$  is connected and  $f : Z \rightarrow X$  is a continuous mapping. If  $g_1, g_2 : Z \rightarrow Y$  are 2 liftings of  $f$  and  $g_1(z_0) = g_2(z_0)$  for some point  $z_0 \in Z$  then  $g_1 = g_2$ .

## Theorem (Uniqueness of Lifting)

Let  $X, Y$  be Hausdorff spaces and  $p : Y \rightarrow X$  be a local homeomorphism. Suppose  $Z$  is connected and  $f : Z \rightarrow X$  is a continuous mapping. If  $g_1, g_2 : Z \rightarrow Y$  are 2 liftings of  $f$  and  $g_1(z_0) = g_2(z_0)$  for some point  $z_0 \in Z$  then  $g_1 = g_2$ .

**Sketch of the proof:** Consider  $T = \{z \in Z : g_1(z) = g_2(z)\}$ .

## Theorem (Uniqueness of Lifting)

Let  $X, Y$  be Hausdorff spaces and  $p : Y \rightarrow X$  be a local homeomorphism. Suppose  $Z$  is connected and  $f : Z \rightarrow X$  is a continuous mapping. If  $g_1, g_2 : Z \rightarrow Y$  are 2 liftings of  $f$  and  $g_1(z_0) = g_2(z_0)$  for some point  $z_0 \in Z$  then  $g_1 = g_2$ .

**Sketch of the proof:** Consider  $T = \{z \in Z : g_1(z) = g_2(z)\}$ .

$T$  is closed: since  $T$  is the preimage of the diagonal  $\Delta \subset Y \times Y$  under the continuous mapping  $(g_1, g_2) : Z \rightarrow Y \times Y$ .

## Theorem (Uniqueness of Lifting)

Let  $X, Y$  be Hausdorff spaces and  $p : Y \rightarrow X$  be a local homeomorphism. Suppose  $Z$  is connected and  $f : Z \rightarrow X$  is a continuous mapping. If  $g_1, g_2 : Z \rightarrow Y$  are 2 liftings of  $f$  and  $g_1(z_0) = g_2(z_0)$  for some point  $z_0 \in Z$  then  $g_1 = g_2$ .

**Sketch of the proof:** Consider  $T = \{z \in Z : g_1(z) = g_2(z)\}$ .

$T$  is closed: since  $T$  is the preimage of the diagonal  $\Delta \subset Y \times Y$  under the continuous mapping  $(g_1, g_2) : Z \rightarrow Y \times Y$ .

$T$  is open: Take  $z_0 \in T$ , let  $y_0 := g_1(z_0) = g_2(z_0)$ .

$p|_V : V \rightarrow U$  is a homeomorphism ( $V$  is a neighborhood of  $y_0$ ). Let  $\phi : U \rightarrow V$  be its inverse.

Let  $W := g_1^{-1}(V) \cap g_2^{-1}(V)$ . Since  $p \circ g_1|_W = p \circ g_2|_W$  then  $g_1|_W = g_2|_W$ . So  $T$  is open.

## The Coverings of Riemann Surfaces

### Lifting of Curves

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a local homeomorphism.

If a curve  $u : I \rightarrow X$  can be lifted to a curve  $\hat{u} : I \rightarrow Y$  then  $\hat{u}$  is uniquely determined once the lifting of a point is specified, for example: the initial point.

## The Coverings of Riemann Surfaces

### Lifting of Curves

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a local homeomorphism.

If a curve  $u : I \rightarrow X$  can be lifted to a curve  $\hat{u} : I \rightarrow Y$  then  $\hat{u}$  is uniquely determined once the lifting of a point is specified, for example: the initial point.

### Theorem (Lifting of Homotopic Curves)

Let  $a, b \in X$  and  $\hat{a} \in p^{-1}(a)$ .

Suppose  $(u_s)_{0 \leq s \leq 1}$  is a homotopy from  $u_0$  to  $u_1$  in  $X$  ( $(u_s)$  are curves from  $a$  to  $b$ ). If each  $u_s$  can be lifted to a curve  $\hat{u}_s$  with initial point  $\hat{a}$ , then  $(\hat{u}_s)_{0 \leq s \leq 1}$  is a homotopy from  $\hat{u}_0$  to  $\hat{u}_1$  in  $Y$ .

### Sketch of the proof:

- ▶ Based on this fact: If  $q : V \rightarrow U$  is a homeomorphism then every continuous map  $f : Z \rightarrow U$  can be lifted to the map  $g : Z \rightarrow V$  given by  $g := q^{-1} \circ f$ .
- ▶ Setting  $A(t, s) := u_s(t)$  and  $\hat{A}(t, s) := \hat{u}_s(t)$ . We shall prove that  $\hat{A}$  is continuous.
- ▶ Take  $U$  a neighborhood of  $a$  and  $V$  a neighborhood of  $\hat{a}$  such that  $p|_V : V \rightarrow U$  is a homeomorphism. Let  $\phi : U \rightarrow V$  be its inverse.
- ▶  $A(\{0\} \times I) = a$  then there exists  $\varepsilon \geq 0$  such that  $A([0, \varepsilon] \times I) \subset U$ . In other words, every curve  $u_s|_{[0, \varepsilon]}$  is in  $U$  so that it can be lifted to the curve  $\phi \circ u_s|_{[0, \varepsilon]}$ . By uniqueness of lifting,  $\hat{u}_s|_{[0, \varepsilon]} = \phi \circ u_s|_{[0, \varepsilon]}$ . Thus  $\hat{A} = \phi \circ A$  on  $[0, \varepsilon] \times I$ .

## Definition

A continuous map  $p: Y \rightarrow X$  is said to have the curve lifting property if the following holds: for every curve  $u$  in  $X$  with initial point  $a$ , for every point  $\hat{a}$  in the fiber  $p^{-1}(a)$ , there exists a lifting  $\hat{u}$  of  $u$  such that its initial point is  $\hat{a}$ .

## Definition

A continuous map  $p: Y \rightarrow X$  is said to have the curve lifting property if the following holds: for every curve  $u$  in  $X$  with initial point  $a$ , for every point  $\hat{a}$  in the fiber  $p^{-1}(a)$ , there exists a lifting  $\hat{u}$  of  $u$  such that its initial point is  $\hat{a}$ .

## Definition (Covering maps)

A continuous map  $p: Y \rightarrow X$  is called a covering map if for every  $x \in X$  there exists an open neighborhood  $U$  of  $x$  such that  $p^{-1}(U)$  is a union of disjoint open sets in  $Y$ , each of which is mapped homeomorphically onto  $U$  by  $p$ .

The special open neighborhoods  $U$  of  $x$  given in the definition are called **evenly covered neighborhoods**. The homeomorphic copies of  $U$  are called the **sheets** over  $U$ .

## Examples

► Let  $k \in \mathbb{N}, k \geq 2$  and  $p_k : \mathbb{C}^* \rightarrow \mathbb{C}^*, z \mapsto z^k$ .

Suppose  $a \in \mathbb{C}^*$  and  $b \in p_k^{-1}(a)$ .

Since  $p_k$  is a local homeomorphism there exists open neighborhoods  $V_0$  of  $b$ ,  $U$  of  $a$  such that  $p_k|_{V_0} : V_0 \rightarrow U$  is a homeomorphism.

Let  $\omega$  be a  $k^{\text{th}}$  primitive root of unity. Then:

$$p_k^{-1}(U) = V_0 \cup \omega V_0 \cup \dots \cup \omega^{(k-1)} V_0$$

## Examples

- ▶ Let  $k \in \mathbb{N}, k \geq 2$  and  $p_k : \mathbb{C}^* \rightarrow \mathbb{C}^*, z \mapsto z^k$ .

Suppose  $a \in \mathbb{C}^*$  and  $b \in p_k^{-1}(a)$ .

Since  $p_k$  is a local homeomorphism there exists open neighborhoods  $V_0$  of  $b$ ,  $U$  of  $a$  such that  $p_k|_{V_0} : V_0 \rightarrow U$  is a homeomorphism.

Let  $\omega$  be a  $k^{\text{th}}$  primitive root of unity. Then:

$$p_k^{-1}(U) = V_0 \cup \omega V_0 \cup \dots \cup \omega^{(k-1)} V_0$$

- ▶  $\exp : \mathbb{C} \rightarrow \mathbb{C}^*$ .

Suppose  $a \in \mathbb{C}^*$  and  $b \in \mathbb{C}$  such that  $\exp(b) = a$ .

Since  $\exp$  is a local homeomorphism there exists open neighborhoods  $V_0$  of  $b$ ,  $U$  of  $a$  such that  $\exp|_{V_0} : V_0 \rightarrow U$  is a homeomorphism.

Then:

$$\exp^{-1}(U) = \bigcup_{n \in \mathbb{Z}} (V_0 + 2\pi in)$$

## Theorem

*Every covering map  $p : Y \rightarrow X$  has the curve lifting property.*

## Theorem

Every covering map  $p : Y \rightarrow X$  has the curve lifting property.

**Sketch of the proof:** Suppose  $u : [0, 1] \rightarrow X$  is a curve and  $y_0 \in Y$  with  $p(y_0) = u(0)$ .

Because of the compactness of  $[0, 1]$  there exists a partition:

$$0 = t_0 < t_1 < \dots < t_n = 1$$

and evenly covered neighborhoods  $U_k \subset X, k = 1, 2, \dots, n$  such that  $u([t_{k-1}, t_k]) \subset U_k$ .

Note that  $p^{-1}(U_k) = \bigcup_{j \in J} V_{kj}$ , where each  $p|_{V_{kj} \rightarrow U_k}$  is a homeomorphism.

In each  $U_k$  the curve  $u([t_{k-1}, t_k])$  can be lifted to the curve  $\hat{u}([t_{k-1}, t_k])$  with  $\hat{u}(t_{k-1})$  is some point in the fiber  $p^{-1}(u(t_{k-1}))$ .

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a covering map.

### Theorem

*If  $X$  is pathwise connected then for any 2 points  $x_0, x_1 \in X$  the sets  $p^{-1}(x_0)$  and  $p^{-1}(x_1)$  have the same cardinality.*

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a covering map.

### Theorem

*If  $X$  is pathwise connected then for any 2 points  $x_0, x_1 \in X$  the sets  $p^{-1}(x_0)$  and  $p^{-1}(x_1)$  have the same cardinality.*

### Proof.

Choose a curve  $u$  in  $X$  joining  $x_0$  to  $x_1$ . Construct  $\varphi : p^{-1}(x_0) \rightarrow p^{-1}(x_1)$  in the following way:

If  $y \in p^{-1}(x_0)$  then there exists a lifting  $\hat{u}$  of  $u$  with  $\hat{u}(0) = y$ . Let  $\varphi(y) := \hat{u}(1) \in p^{-1}(x_1)$ . The uniqueness of lifting implies that  $\varphi$  is bijective. □

## Definition

The cardinality of  $p^{-1}(x)$  for  $x \in X$  is called the number of sheets of the covering  $p$ .

## Definition

The cardinality of  $p^{-1}(x)$  for  $x \in X$  is called the number of sheets of the covering  $p$ .

## Example

- ▶  $z \mapsto z^k$  is a  $k$ -sheeted covering.
- ▶  $\exp : \mathbb{C} \rightarrow \mathbb{C}^*$  has an infinite number of sheets.

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a covering map. If  $Z$  is another topological space and  $f : Z \rightarrow X$  is a continuous map. Question: Under which conditions of  $Z$ , the map  $f$  can be lifted to a continuous map  $g : Z \rightarrow Y$ ?

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a covering map. If  $Z$  is another topological space and  $f : Z \rightarrow X$  is a continuous map. Question: Under which conditions of  $Z$ , the map  $f$  can be lifted to a continuous map  $g : Z \rightarrow Y$ ?

### Theorem (Lifting of Mappings)

*If  $Z$  is simply connected, pathwise connected and locally pathwise connected, then for every choice of points  $z_0 \in Z$  and  $y_0 \in Y$  with  $f(z_0) = p(y_0)$  there exists precisely one lifting  $\hat{f} : Z \rightarrow Y$  such that  $\hat{f}(z_0) = y_0$ .*

Suppose  $X, Y$  are Hausdorff spaces and  $p : Y \rightarrow X$  is a covering map. If  $Z$  is another topological space and  $f : Z \rightarrow X$  is a continuous map. Question: Under which conditions of  $Z$ , the map  $f$  can be lifted to a continuous map  $g : Z \rightarrow Y$ ?

### Theorem (Lifting of Mappings)

*If  $Z$  is simply connected, pathwise connected and locally pathwise connected, then for every choice of points  $z_0 \in Z$  and  $y_0 \in Y$  with  $f(z_0) = p(y_0)$  there exists precisely one lifting  $\hat{f} : Z \rightarrow Y$  such that  $\hat{f}(z_0) = y_0$ .*

**Sketch of the proof:** Suppose  $z \in Z$  is an arbitrary point and  $u : I \rightarrow Z$  is a curve from  $z_0$  to  $z$ . Then  $v := f \circ u$  is a curve in  $X$  with initial point  $f(z_0)$  and end point  $f(z)$ .

Let  $\hat{v} : I \rightarrow Y$  be the unique lifting of  $v$  which has initial point  $y_0$ . Define  $\hat{f}(z) := \hat{v}(1) \in Y$ . This definition is independent of the choice of the curve  $u$ , hence  $\hat{f}$  is a well-defined mapping from  $Z$  to  $Y$ . Also by construction  $f = p \circ \hat{f}$ .

Need to show that  $\hat{f}$  is continuous.

Let  $z \in Z, x = f(z), y = \hat{f}(z)$  and  $V$  be an open neighborhood of  $y$ . It suffices to show that there is an open neighborhood  $W$  of  $z$  such that  $\hat{f}(W) \subset V$ .

Need to show that  $\hat{f}$  is continuous.

Let  $z \in Z, x = f(z), y = \hat{f}(z)$  and  $V$  be an open neighborhood of  $y$ . It suffices to show that there is an open neighborhood  $W$  of  $z$  such that  $\hat{f}(W) \subset V$ .

Without loss of generality, we can assume that  $p|_V : V \rightarrow U$  is a homeomorphism, let  $\varphi : U \rightarrow V$  be its inverse.

Since  $f$  is continuous, there exists  $W'$  open neighborhood of  $z$  such that  $f(W') \subset U$ .  $Z$  is locally pathwise connected, there exists a pathwise connected subset  $W$  of  $W'$  containing  $z$ .

Need to show that  $\hat{f}$  is continuous.

Let  $z \in Z, x = f(z), y = \hat{f}(z)$  and  $V$  be an open neighborhood of  $y$ . It suffices to show that there is an open neighborhood  $W$  of  $z$  such that  $\hat{f}(W) \subset V$ .

Without loss of generality, we can assume that  $p|_V : V \rightarrow U$  is a homeomorphism, let  $\varphi : U \rightarrow V$  be its inverse.

Since  $f$  is continuous, there exists  $W'$  open neighborhood of  $z$  such that  $f(W') \subset U$ .  $Z$  is locally pathwise connected, there exists a pathwise connected subset  $W$  of  $W'$  containing  $z$ .

Now we claim that  $\hat{f}(W) \subset V$ . Let  $z' \in W$  be an arbitrary point and  $u'$  be a curve from  $z$  to  $z'$  which lies entirely in  $W$ . Then the curve  $v' = f \circ u'$  lies entirely in  $U$ , we let  $\hat{v}' := \varphi \circ v'$  be a lifting of  $v'$  with initial point  $y$ .

Note that  $\hat{v} \cdot \hat{v}'$  is the lifting of  $v \cdot v' = f \circ (u \cdot u')$  with initial point  $y_0$ . Thus

$$\hat{f}(z') = (\hat{v} \cdot \hat{v}')(1) = \hat{v}'(1) \in V$$

Need to show that  $\hat{f}$  is continuous.

Let  $z \in Z, x = f(z), y = \hat{f}(z)$  and  $V$  be an open neighborhood of  $y$ . It suffices to show that there is an open neighborhood  $W$  of  $z$  such that  $\hat{f}(W) \subset V$ .

Without loss of generality, we can assume that  $p|_V : V \rightarrow U$  is a homeomorphism, let  $\varphi : U \rightarrow V$  be its inverse.

Since  $f$  is continuous, there exists  $W'$  open neighborhood of  $z$  such that  $f(W') \subset U$ .  $Z$  is locally pathwise connected, there exists a pathwise connected subset  $W$  of  $W'$  containing  $z$ .

Now we claim that  $\hat{f}(W) \subset V$ . Let  $z' \in W$  be an arbitrary point and  $u'$  be a curve from  $z$  to  $z'$  which lies entirely in  $W$ . Then the curve  $v' = f \circ u'$  lies entirely in  $U$ , we let  $\hat{v}' := \varphi \circ v'$  be a lifting of  $v'$  with initial point  $y$ .

Note that  $\hat{v} \cdot \hat{v}'$  is the lifting of  $v \cdot v' = f \circ (u \cdot u')$  with initial point  $y_0$ . Thus

$$\hat{f}(z') = (\hat{v} \cdot \hat{v}')(1) = \hat{v}'(1) \in V$$

. **Remark** The theorem still holds when  $p$  is just a local homeomorphism with curve lifting property.

## Example (The Logarithm of a Function)

Suppose  $X$  is a simply connected Riemann surface and  $f : X \rightarrow \mathbb{C}^*$  is a nowhere vanishing holomorphic function on  $X$ .

We want to find the logarithm of  $f$ , i.e., find a holomorphic function  $F : X \rightarrow \mathbb{C}$  such that  $\exp(F) = f$ . But this just means that  $F$  is a lifting of  $f$  with respect to the covering  $\exp : \mathbb{C} \rightarrow \mathbb{C}^*$ .

$$\begin{array}{ccc} & & \mathbb{C} \\ & \nearrow F & \downarrow \exp \\ X & \xrightarrow{f} & \mathbb{C}^* \end{array}$$

## Example (The Logarithm of a Function)

Suppose  $X$  is a simply connected Riemann surface and  $f : X \rightarrow \mathbb{C}^*$  is a nowhere vanishing holomorphic function on  $X$ .

We want to find the logarithm of  $f$ , i.e., find a holomorphic function  $F : X \rightarrow \mathbb{C}$  such that  $\exp(F) = f$ . But this just means that  $F$  is a lifting of  $f$  with respect to the covering  $\exp : \mathbb{C} \rightarrow \mathbb{C}^*$ .

$$\begin{array}{ccc} & & \mathbb{C} \\ & \nearrow F & \downarrow \exp \\ X & \xrightarrow{f} & \mathbb{C}^* \end{array}$$

By the theorem above, for each  $x_0 \in X$  and  $c \in \mathbb{C}$  such that  $\exp(c) = f(x_0)$  there exists a lifting  $F : X \rightarrow \mathbb{C}$  with  $F(x_0) = c$ . Since  $\exp$  and  $f$  are holomorphic,  $F$  is also holomorphic. Moreover, any other solution of the problem differs from  $F$  by an additive constant  $2\pi in, n \in \mathbb{Z}$ .

## Example (The Logarithm of a Function)

Suppose  $X$  is a simply connected Riemann surface and  $f : X \rightarrow \mathbb{C}^*$  is a nowhere vanishing holomorphic function on  $X$ .

We want to find the logarithm of  $f$ , i.e., find a holomorphic function  $F : X \rightarrow \mathbb{C}$  such that  $\exp(F) = f$ . But this just means that  $F$  is a lifting of  $f$  with respect to the covering  $\exp : \mathbb{C} \rightarrow \mathbb{C}^*$ .

$$\begin{array}{ccc} & & \mathbb{C} \\ & \nearrow F & \downarrow \exp \\ X & \xrightarrow{f} & \mathbb{C}^* \end{array}$$

By the theorem above, for each  $x_0 \in X$  and  $c \in \mathbb{C}$  such that  $\exp(c) = f(x_0)$  there exists a lifting  $F : X \rightarrow \mathbb{C}$  with  $F(x_0) = c$ . Since  $\exp$  and  $f$  are holomorphic,  $F$  is also holomorphic. Moreover, any other solution of the problem differs from  $F$  by an additive constant  $2\pi in, n \in \mathbb{Z}$ .

When  $X$  is a simply connected domain in  $\mathbb{C}^*$ , we let  $j : X \rightarrow \mathbb{C}^*$  be the canonical injection. Then every lifting of  $j$  with respect to  $\exp$  is a branch of the function  $\log$  on  $X$ .

## Theorem

Suppose  $X$  is a manifold,  $Y$  is a Hausdorff space and  $p : Y \rightarrow X$  is a local homeomorphism with the curve lifting property. Then  $p$  is a covering map.

## Theorem

Suppose  $X$  is a manifold,  $Y$  is a Hausdorff space and  $p : Y \rightarrow X$  is a local homeomorphism with the curve lifting property. Then  $p$  is a covering map.

## Proof.

Take  $x \in X$  and let  $p^{-1}(x) = \{y_j : j \in J\}$ .

Let  $U$  be an open ball centered at  $x$  and  $f : U \rightarrow X$  be the canonical injection. By "Lifting of Mappings Theorem", for every  $j \in J$  there exists a lifting  $\hat{f}_j : U \rightarrow Y$  such that  $\hat{f}_j(x) = y_j$ .

Let  $V_j := \hat{f}_j(U)$ , we can easily show that:

$$p^{-1}(U) = \bigcup_{j \in J} V_j$$

## Definition

- ▶ A locally compact space is a Hausdorff space such that every point has a compact neighborhood.
- ▶ A proper mapping is a continuous mapping between 2 locally compact spaces such that the preimage of every compact set is compact

## Definition

- ▶ A locally compact space is a Hausdorff space such that every point has a compact neighborhood.
- ▶ A proper mapping is a continuous mapping between 2 locally compact spaces such that the preimage of every compact set is compact

**Remark** Suppose  $X, Y$  are locally compact spaces and  $p : Y \rightarrow X$  is a proper, discrete map. Then:

- ▶  $p$  is a closed map.
- ▶ For every  $x \in X$ , the set  $p^{-1}(x)$  is finite.
- ▶ If  $V$  is a neighborhood of  $p^{-1}(x)$ , then there exists a neighborhood  $U$  of  $x$  with  $p^{-1}(U) \subset V$ .

## Theorem

If  $X, Y$  are locally compact spaces and  $p : Y \rightarrow X$  is a proper local homeomorphism, then  $p$  is a covering map.

## Proof.

Suppose  $x \in X$  is arbitrary and let  $p^{-1}(x) = \{y_1, \dots, y_n\}$ .

For every  $1 \leq j \leq n$  there exists an open neighborhood  $W_j$  of  $y_j$  and an open neighborhood  $U_j$  of  $x$  such that  $p|W_j \rightarrow U_j$  is a homeomorphism.

We may assume that  $W_j$  are pairwise disjoint.

Since  $W_1 \cup \dots \cup W_n$  is a neighborhood of  $p^{-1}(x)$ , there exists an open neighborhood  $U \subset U_1 \cap \dots \cap U_n$  of  $x$  with  $p^{-1}(U) \subset W_1 \cup \dots \cup W_n$ .

Let  $V_j := W_j \cap p^{-1}(U)$ , then the  $V_j$  are disjoint open sets and

$$p^{-1}(U) = V_1 \cup \dots \cup V_n$$

and all the mappings  $p|V_j \rightarrow U$  are homeomorphism. □

## The Coverings of Riemann Surfaces

### Proper Holomorphic Mappings

Suppose  $X$  and  $Y$  are Riemann surfaces and  $f : X \rightarrow Y$  is a proper, non-constant holomorphic mapping.

**Remark** The set  $A$  of branch points of  $f$  is closed and discrete. Thus  $B := f(A)$  is also closed and discrete.  $B$  is called the set of **critical values** of  $f$ .

Let  $Y' := Y \setminus B$  and  $X' := X \setminus f^{-1}(B)$ . Then  $X', Y'$  are Riemann surfaces and  $f|_{X'} : X' \rightarrow Y'$  is a proper, non-constant, unbranched holomorphic map. Then  $f|_{X'}$  is a covering map, it has a well-defined number of sheets  $n$ . In other words, for every value  $y \in Y'$  is taken exactly  $n$  times on  $X'$  by the map  $f$ .

We want to extend this statement to the critical values  $b \in B$  as well. It leads us to the notion of the ramification order of a point. For  $x \in X$  we denote by  $v(f, x)$  the ramification order of the point  $x$  (it means that  $f$  takes the value  $f(x)$  at the point  $x$  with multiplicity  $v(f, x)$ ). We will say that  $f$  takes the value  $c \in Y$ , counting multiplicities,  $m$  times on  $X$  if

$$m = \sum_{x \in p^{-1}(c)} v(f, x).$$

## Theorem

Suppose  $X, Y$  are Riemann surfaces and  $f : Y \rightarrow X$  is a proper, non-constant holomorphic mapping. Then there exists a natural number  $n$  such that  $f$  takes every value  $c \in X$ , counting multiplicities,  $n$  times.

## Proof.

Let  $n$  be the number of sheets of the unbranched covering  $f|_{X'} : X' \rightarrow Y'$ . Suppose  $b \in B$  is a critical point.

Let  $p^{-1}(b) = \{x_1, x_2, \dots, x_r\}$  and  $v(f, x_j) =: k_j$ . We only need to show that

$$k_1 + k_2 + \dots + k_r = n$$

By the "Local Behavior Theorem", there exists disjoint open neighborhoods  $U_j$  of  $x_j$  and open neighborhoods  $V_j$  of  $b$  such that: For each  $j$ , for every point  $c \in V_j \setminus \{b\}$  the set  $f^{-1}(c) \cap U_j$  consists of exactly  $k_j$  points.

Because  $f$  is proper, we can find a neighborhood  $V \subset V_1 \cap V_2 \cap \dots \cap V_r$  of  $b$  such that  $f^{-1}(V) \subset U_1 \cup U_2 \cup \dots \cup U_r$ . Then for every point  $c \in V \cap Y'$  we have  $f^{-1}(c)$  consists of  $k_1 + k_2 + \dots + k_r$  points. On the other hand,  $\forall c \in Y'$  the cardinality of  $f^{-1}(c)$  is equal to  $n$ . Thus

$$n = k_1 + k_2 + \dots + k_r.$$

### Corollary

*On any compact Riemann surface  $X$  every non-constant meromorphic function has as many zeros as poles, where each is counted according to multiplicities.*

### Corollary

*There does not exist any meromorphic function on the complex torus  $\mathbb{C}/\Gamma$  which has a single pole of first order.*

## Riemann-Hurwitz Theorem

## The Euler Characteristic

Let  $S$  be a compact differentiable orientable surface. Denote by  $\Delta$  the standard triangle of vertices  $(0, 0)$ ,  $(1, 0)$  and  $(0, 1)$  in  $\mathbb{R}^2$ . We call a topological triangle of  $S$  the image of  $\Delta$  by a homeomorphism  $\varphi : \Delta \rightarrow S$ . The images of vertices and edges by  $\varphi$  will be called vertices and edges of the triangle  $\varphi(\Delta)$

## Riemann-Hurwitz Theorem

### The Euler Characteristic

Let  $S$  be a compact differentiable orientable surface. Denote by  $\Delta$  the standard triangle of vertices  $(0, 0)$ ,  $(1, 0)$  and  $(0, 1)$  in  $\mathbb{R}^2$ . We call a topological triangle of  $S$  the image of  $\Delta$  by a homeomorphism  $\varphi: \Delta \rightarrow S$ . The images of vertices and edges by  $\varphi$  will be called vertices and edges of the triangle  $\varphi(\Delta)$ .

A triangulation of  $S$  is a finite family of triangles  $\Delta_i \subset S$  whose union is equal to  $S$  such that the intersection of two different triangles is either empty, a common edge or a common vertex.

## Riemann-Hurwitz Theorem

### The Euler Characteristic

A triangulation of  $S$  is a finite family of triangles  $\Delta_i \subset S$  whose union is equal to  $S$  such that the intersection of two different triangles is either empty, a common edge or a common vertex.

### Theorem (Radó)

*Any compact surface admits a triangulation.*

## Riemann-Hurwitz Theorem

### The Euler Characteristic

#### Theorem

*For every triangulation of  $S$ , the number of vertices, minus the number of edges and plus the number of triangles, does not depend on the triangulation. This number, denoted by  $\chi$ , is called the Euler characteristic of  $S$ . Moreover, we also have  $\chi = 2 - 2g$  where  $g$  is the genus of the surface.*

## Riemann-Hurwitz Theorem

### Riemann-Hurwitz formula

Let  $X, Y$  be compact Riemann surfaces and  $f : X \rightarrow Y$  is a non-constant holomorphic mapping.

Since  $X$  is compact,  $f$  is proper and hence it is a branched covering. We call the number  $n$  defined as above the degree of  $f$ .

For each ramification point  $x \in X$ , let  $o(x)$  be its ramification order.

### Theorem (Riemann-Hurwitz)

$$\chi(X) = n\chi(Y) - \sum(o(x) - 1)$$

THANK YOU FOR LISTENING
